Parameter	Value	
Hardware	ARTIX-7 A200T FPGA based	
	baseband card	
MODEM	8PSK-TCM	
Modem Rate	555Kbps	
SNR	7.6 db at 1e5	
Channel (V/UH	F) 30Mhz - 512Mhz	
Bandwidth	250khz	
Bit Duration	2.7us	
Throughput	100kbps (Throughput at	
	application Layer)	
Ramp up time	116 us (Junk symbols will be	
	sent)	
Propagation De	lay 00 us (Junk symbols will be	
	sent)	
Training sequer	ce 421.2us(provided time for	
	training sequence)	
Frame Slot	2 ms	
Frame SOM	8 bytes	
Payload	32 bytes (692 us)	

TABLE 0

# 1.2 Sequence of Steps

- 1) Simulation of suitable Preamble detection algorithm.
- 2) Simulation of suitable channel estimation and equalization algorithms for mitigating Rayleigh fading channel effects.
- 3) Simulation of suitable timing and frequency algorithms for narrow band waveform (coherent TCM-8PSK). Convergence of timing, frequency and equalization algorithms in limited preamble symbols provided (19.5 bytes which is equal to 156 bits or 78 symbols for TCM 8PSK modulation) and efficient uti-

lization of hardware resources (required all these algorithms shall take max 40% of FPGA resources).

- 4) Performance evaluation and Simulation of equalizer and synchronization algorithms should to be done in fixed point.
- MATLAB codes should be hardware implementable and consider FPGA resources restrictions. Matrix inversions in MATLAB code should not be there.

# 1.3 Technology Overview

Preamble detection can be done using a special kind of correlation as in [1]. A symbol detection technique in the presence of time offsets is available in [2]. A correlation based technique for frequency offset estimation is provided in [3]. A DFSE based equalization technique based on the Viterbi algorithm is provided in [4]. A constant modulus decision directed algorithm is proposed in [5]. A channel impulse response based sparse equalization and synchronization technique is given in [6]. Blind equalization techniques are listed in [7].

All the above techniques will be analyzed before before finalizing the algorithms for preamble detection, synchronization and equalization.

# 2 Frame Synchronization

2.1 Frame Synchronization : Global Summation of SOF/PLSC Detectors

Let the frequency offset be  $\Delta f$  and phase offset be  $\Delta \phi$ . Then,

$$Y_k = X_k e^{j(2\pi\Delta f kM + \phi_k)} + V_k, \quad k = 1, \dots, N$$
 (2.1.1)

assuming that no pilot symbols are trasmitted. Let the phase information be  $\theta_k$ , and defined as

$$e^{\theta(k)} = \frac{Y_k}{|Y_k|} \tag{2.1.2}$$

At the receiver, the header information is available in the form of

$$g_i(l) = x_s(l)x_s(l-i), l = 0, \dots, SOF - 1$$
 (2.1.3)

$$h_i(l) = x_p(l)x_p(l-i), l = 0, \dots, PLSC - 1$$
 (2.1.4)

where  $x_s$  are the mapped SOF symbols,  $x_p$  are the scrambled PLSC symbols, both modulated using 8-PSK for i = 1, 2, 4, 8, 16, 32. The SOM is choosen

as a 64-bit length such that SOF and PLS each are of 32-bit length.

A special kind of correlation is performed to obtain

$$m_i(k) = \sum_{l=0}^{PLSC-1} e^{j(\theta(k-l) - \theta(k-l-i))} h_i(l), \qquad (2.1.5)$$

$$n_i(k) = \sum_{l=0}^{SOF-1} e^{j(\theta(k-l) - \theta(k-l-i))} g_i(l), \qquad (2.1.6)$$

$$k = 1, \dots, N \tag{2.1.7}$$

Compute

$$p_{i}(k) = \begin{cases} \max(|n_{i}(k - PLSC) + m_{i}(k)|, \\ |n_{i}(k - PLSC) - m_{i}(k)|) & k > PLSC \end{cases}$$
(2.1.8)

GLOBAL variable  $G_{R,T}(k)$  [1] defined as,

$$G_{R,T}(k) = \sum_{i>1} p_i(k), \quad i = 1, 2, 4, 8, 16, 32 \quad (2.1.9)$$

At the receiver, let us consider we have sent two types of transmission. One is PLHEADER+DATA  $(Y_{k1})$  and another is only DATA  $(Y_{k2})$  and the GLOBAL variables for  $(Y_{k1})$  and  $(Y_{k2})$  from (2.1.9) are  $G1_{R,T}(k)$ ,  $G2_{R,T}(k)$  respectively.

2.1.1 Global Threshold Calculation: The Global Threshold variable is defined as

$$T = \max (\max (G1_{R,T}(k)), \max (G2_{R,T}(k)))$$
(2.1.10)

The probability of false detection of plheader when only DATA frame  $(Y_{k2})$  has been sent is defined as

$$P_{FA} = \frac{\sum \frac{sign(|Y_{k2} - T|) + 1}{2}}{N}$$
 (2.1.11)

The probability of missed detection of plheader when PLHEADER+DATA  $(Y_{k1})$  has been sent is defined as

$$P_{MD} = \frac{\sum \frac{sign(T - |Y_{k1}|) + 1}{2}}{N + PLSC + SOF}$$
 (2.1.12)

# 2.2 Plots

Fig.5 shows the ROC curve  $(P_{FA}vsP_{MD})$  at the receiver for frame synchronization at  $\frac{E_b}{N_0} = -2$  dB and with a frequency offset of 250 KHz.
